

This technical note illustrates many of the most common flashing details for commercial buildings. The purpose for flashing is to direct moisture to the exterior and in so doing, prevent moisture from deteriorating steel angles or other building components. The following details were designed to accomplish both goals. Modifications to these details are normal, however, the changes should always focus on the primary objectives for flashing.

**THE RESPONSIBILITY FOR SPECIFYING THESE ALTERNATIVES BELONGS TO THE DESIGNER OR ENGINEER**

**General Considerations Pertaining to Flashing Installation**

- When flashing needs splicing, the ends should be overlapped a minimum of 100 mm and sealed with a compatible mastic.
- Corner flashing also requires sealing overlapping ends.
- Watertight end dams are suggested where horizontal flashing terminates.
- Flashing generally should extend 200 mm above the bottom of the flashing and be fastened to the backup.
- Through wall flashing at the base of the walls should be located 150 mm above finished grade.
- Any cavity space below the flashing at the wall base should be completely filled with mortar.
- When flashing is placed over a brick, block, or concrete wall adjacent to habitable rooms, a thin bed of mortar or compatible mastic must be spread onto the brick, block, or concrete walls before the flashing is set in place.
- Flashing should be noncorrosive and nonstaining. Copper and galvanized steel may stain adjacent masonry. Copper and stainless steel require a protective material when they are placed next to a steel angle.
- Impregnated felt, polyethylene, aluminum or lead should not be used as flashing.

**Special Considerations Pertaining to Flashing Installation**

Brick industry standards and some building codes require the flashing to project 5 mm past the face of the brick.

**Advantages and Disadvantages of Elastomeric Versus Composite Flashing**

There are several generic types of through-wall flashing, specifically, rubber, metal, and composite. The most commonly used elastomeric flashing is EPDM, which normally is a cured product, manufactured in 40 mil (1 mm) thickness. Metal flashings are copper or stainless steel. Composite flashings come in a variety of materials. Typically they have a copper core material, covered by asphalt, kraft paper or polyethylene films. Each type has advantages and disadvantages as shown in the table on the next page.

Elastomeric flashing is easier to bend, mold and seal at corners and end dams than composite flashing. When flashing needs to span across a cavity, composite flashing is more effective since elastomeric flashing will sag and eventually tear from sustained weight. If anchors need to penetrate the flashing, a thick elastomeric flashing will seal better around the anchor than composite flashing.

There are potential problems with the compatibility between the flashing that extends to the face of the brick and the sealant that seals the space between the underside of the flashing and the top of the brick. This note refers to detail 26 & 27.

	ADVANTAGES	DISADVANTAGES
EPDM	a. Flexible b. Easily spliced	a. Not as strong as metal or composite flashing b. Compatibility of sealant and flashing needs to be verified
Metal	a. Strong b. Can span the cavity without support c. Compatible with most sealants	a. Expensive b. Hard to splice c. May corrode when in contact with the shelf angle
Composite	a. Strong b. Can span the cavity without support	a. Expensive b. The asphalt-coated flashings are not compatible with most sealants c. Coatings may delaminate from the core

The following drawings show two possible flashing details using EPDM and the composite flashing. The first detail, below, shows a horizontal movement joint using EPDM flashing material. The angle is installed with the vertical leg down so that the flashing can not tear on the anchor bolt nut. This detail could also work with metal, copper or stainless steel flashing, provided that there is a rubber or composite material separating the metal flashing from the steel angle, similar to the next detail. This flashing detail could be used with a lintel just as it is used with the shelf angle.

The second detail, above, also shows a horizontal movement joint, but the through-wall flashing is composite flashing. Few sealants adhere effectively to bitumen coated flashing. If the flashing has kraft paper or polyethylene film, these coatings may delaminate. In order to overcome these problems, a bent metal drip edge, copper or stainless steel, is installed under the composite flashing so that the sealant at the brick face will have compatible surface to adhere to. In addition, the metal drip edge can not sit directly on the shelf angle; otherwise, one of the metals may corrode. Therefore, an additional piece of either rubber or composite flashing, a separator, is needed between the metal drip edge and the shelf angle. The metal drip edge can also be used with the EPDM through wall flashing.

The table below shows alternative sealants that have been tested for compatibility with different EPDM flashing materials.

Sealant	EPDM	
	Carlisle Pre-Kleened	Firestone Flash Guard
Pecora #895 Silicone	No Primer Necessary	P-120 Primer
Dow Corning #790 Silicone*	No Primer Necessary	No Primer Necessary

\*Does not effectively adhere to copper.

When the composite flashing sits on the metal drip edge, no sealant is needed between the two materials. When EPDM sits on the metal drip edge; Carlisle recommends "Secure Tape", Firestone recommends "Flashguard Adhesive Tape".

The sealants listed for the EPDM flashing will adhere to the drip edge and the brick. However, sealants adhere differently to different absorption rate brick, therefore, the brick adhesion should be field-tested as described below.

In addition EPDM flashing with primers applied may require adhesion testing to verify the compatibility of the sealant and the primer.

Whatever sealants are used for the horizontal, or vertical control joints, it is important that actual field-testing of the sealants adhesion to the flashing and to the brick be done.

A simple hand pull test can be used at the job site after the sealant is fully cured (usually within 7 to 21 days). It is suggested that 10 tests for the first 300 m and one test per 300 m thereafter or one test per floor per elevation be performed. The hand pull test procedure is as follows:

1. Make a knife cut horizontally from one side of the joint to the other.
2. Make two vertical cuts (from the horizontal cut) approximately 75 mm long, at both sides of the joint.
3. Place a 25 mm mark on the sealant tab.
4. Grasp the 50 mm piece of sealant firmly just beyond the 25 mm mark and pull at a 90° angle. If the sealant itself tears, then the adhesion to the flashing is adequate.

5. If dissimilar substrates are being sealed, check the adhesion of sealant to each substrate separately. This is accomplished by extending the vertical cut along one side of the joint, checking adhesion to the opposite side, and then repeating for the other surface.
6. Check with sealant manufacturer for suggested allowable extensions.

### Exterior Corner Flashing Detail - Steel & Concrete Columns - Block Backup

Note: Brick anchors & insulation have been omitted for clarity.

Note: Sealant goes around the bearing end of the angle and provides a protective barrier from moisture.

Flashing Termination at End of Lintel  
(End Dam on Lintel Detail)

Detail 23 - End Dams

Note: This detail may occur at windows, doors, and where shelf angle stops at vertical control joints.

Detail 24 - Shelf Angle

Note: Brickwork supported on shelf angle positioned below support beam. Support beam could be concrete. Block backup could be metal studs. Anchors omitted for clarity.

Detail 25 - Alternate Shelf Angle

Note: Anchors omitted for clarity.

Detail 26 - Enlarged View of Shelf Angle

Detail 27 - Alternate to Detail 26

Note: Refer to note on "compatibility between flashing and sealant."

Coping Details, see next page.

## Coping Details

Detail 28 - Stone Coping

Note: Dowel which penetrates flashing must be sealed. Flashing at top of wall at corners must be lapped and sealed similar to detail 29. Mortar can replace backer rod & sealant on top of brick provided brick is supported by a shelf angle attached to building frame at the roof line. Flashing covering cavity should be composite /metal.

Detail 30 - Metal Coping

Note: This same detail may be used with metal studs as backup instead of concrete block.

Detail 29 - Corner Flashing

Detail 31 - Garden Wall Coping

Note: It is conservative to provide vertical control joints at approximately 6 to 8 m. If flashing is installed, corners require the flashing to be lapped. Northern climates the copings should have an overhang and a drip groove.
